

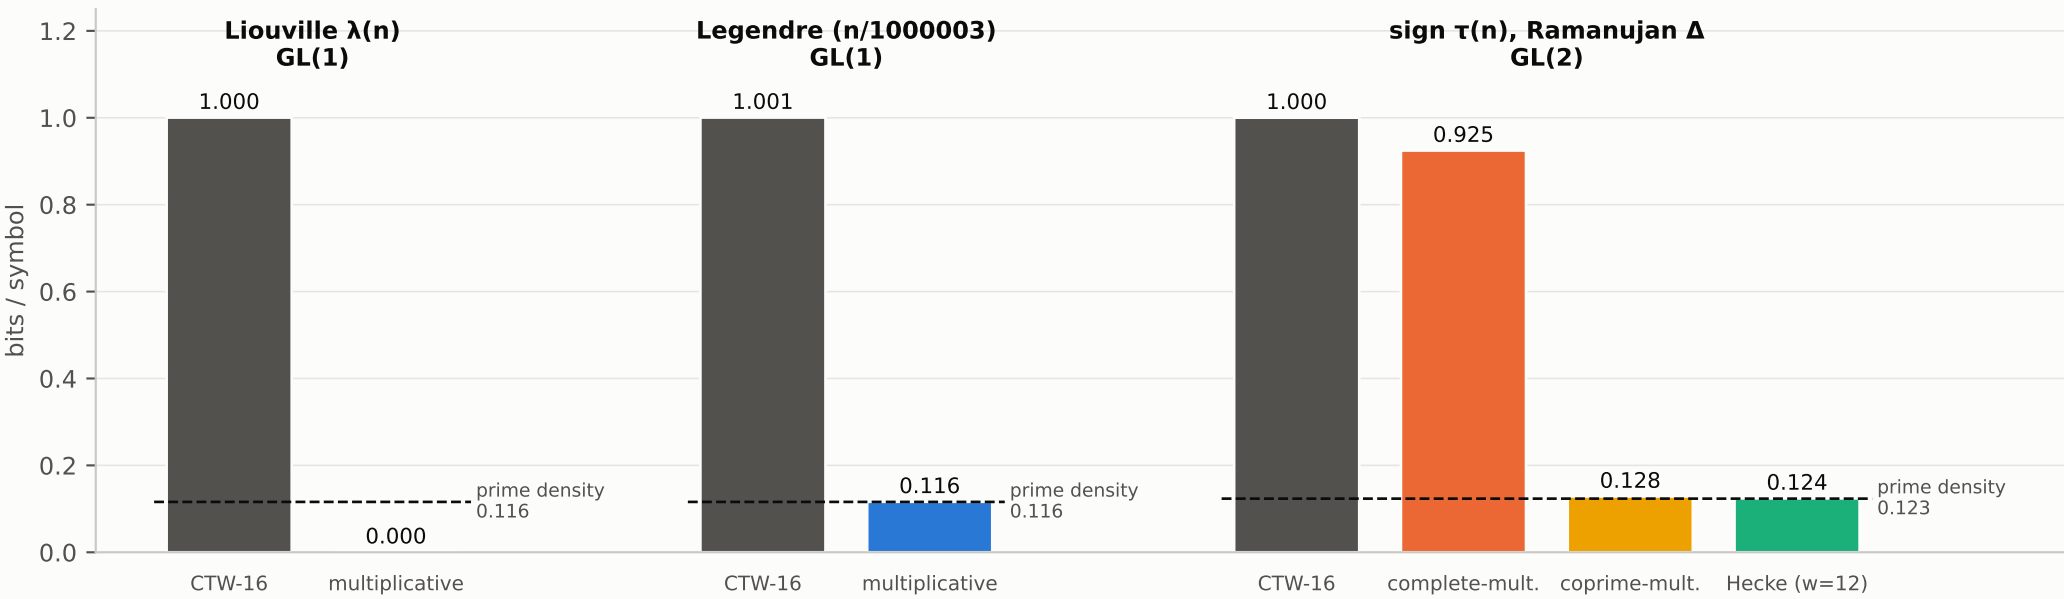

Fig. 5 · Climbing the Langlands ladder: the primes carry all the information

E002B, E004. Generic observers see pure noise (≈ 1 bit/symbol; Sarnak-style pseudorandomness). Observers that know the multiplicative structure pay exactly the prime density. On GL(2) a program search on $n \leq 2000$ rejects complete multiplicativity (59% of pairs), accepts coprime multiplicativity (100% of 3406) and finds the unique weight $w = 12$; the coprime-only observer pays the prime-POWER density (0.128). Ledger on $n \in (2000, 4000]$.
